If G, H are graphs, a function $f: E(G) \rightarrow E(H)$ is called cycle-continuous if the pre-image of every element of the (binary) cycle space of H is a member of the cycle space of G .

Problem Does there exist an infinite set of graphs $\{G_1, G_2, \dots\}$ so that there is no cycle continuous mapping between G_i and G_j whenever $i \neq j$?
